

Traffic Light Model Description

Lecture 62, v01

A description of a model developed by The MathWorks

Purpose

- This lecture describes the Traffic Light system model developed by The Mathworks
- The description of the model is conducted in three sections
 - A top level view of the major model elements (Section 1)
 - A mid-level description of the Traffic Controller Stateflow model (Section 2)
 - A detailed, low-level description of the piece parts that make up the model, and how they communicate with each other (Section 3)
- The vast majority of the material contained herein to describe this model is sourced from various pages on www.mathworks.com
- The copyright applied to this document refers to the arrangement of data collected from The MathWorks in a format that is appropriate to covering the subject in a 1- to 2-week educational module

Section 1

Traffic Light System Overview

Traffic Light Model (sf_traffic_light.slx)

- This model represents a simple Traffic Light system at the intersection of two 1-way roads controlled by a Stateflow model of a Traffic Controller

- Shown in the diagram on the right is the Simulink portion of the model
- It includes a Stateflow model that contains logic that controls the state transitions of two semaphores containing three colored lights (Red, Green, Yellow)
- The Stateflow model lies beneath a Stateflow “mask” shown to the right in beige fill

Simulink Model Component Descriptions

- Car Monitors (x 2)
 - Generates cars to occupy the intersection from each direction
 - Monitors the state of the Semaphore in each direction (Red, Yellow, or Green state)
- Car Counters (x 2)
 - Shows the number of cars at the intersection in each direction
- Traffic Controller
 - Stateflow model that executes two Statecharts, one for each direction
 - Based on the number of cars in the intersection, determines the state that each Semaphore should be in
 - Outputs Light 1 and Light 2 which controls which color of light the Semaphore must display
 - Supplies this Semaphore state data to the Car Monitors
- Traffic Semaphores (Lights) (x 2)
 - Implements the display of lights (Red, Yellow, or Green) depending on the signal provided by the Traffic Controller
- Safety Assertion
 - Ensures that two green lights cannot be ON at the same time

Beneath Traffic Controller “Mask”

- The Stateflow chart Traffic Controller manages two traffic controllers in parallel
- Each controller determines the phase of the downstream traffic light based on
 - Traffic congestion at the intersection
 - An input from Simulink
 - Parameters on the chart’s “mask”
- Beneath the Stateflow “mask” in the Simulink model (the Traffic Controller) lies the Controller
 - This is accessed by clicking on the small arrow at the lower left of the Traffic Controller
- The Controller contains two Subcharts, one for each traffic direction
 - Light1Controller
 - Light2Controller

Section 2

Traffic Controller Stateflow Model

Stateflow Model of Traffic Light State Behavior

- This Stateflow model for Light1Controller and Light2Controller are identical
- The two subcharts have an identical hierarchy consisting of three child states: Red, Yellow, and Green
- The output data Light1 and Light2 (not shown in this view) correspond to the active child states in the subcharts
- These output signals:
 - Determine the phase (light color) of the Semaphores
 - Contribute to the generation of cars waiting at each light
 - Drive the Safety Assertion subsystem verifying that the two traffic lights are never simultaneously green

When on Statechart is guarding certain transitions, it is checking the conditions of the other Statechart

Example, in going from Red to Green:
[~greenLightLocked] is determining whether the other Statechart has gone Red, since the data store memory (flag) greenLightLocked is cleared on exit from the Yellow state

Light Controller Parameters Definition

- This table defines the meanings of the parameters used in the two Light Controllers

Parameter	Preset Value	Definition
REDDELAY	6 seconds	Length of time before the controller begins to check for cars at the intersection Also, minimum length of time before the traffic light can turn green after the controller requests a green light
MAXREDDelay	360 seconds	Maximum length of time that the controller checks for cars before requesting a green light
GREENDELAY	180 seconds	Maximum length of time that the traffic light remains green
MINGREENDELAY	120 seconds	Minimum length of time that the traffic light remains green
YELLOWDELAY	15 seconds	Length of time that the traffic light remains yellow

Behavior of Traffic Controller Subcharts

- Each traffic controller cycles through its child states, from Red to Green to Yellow and back to Red
 - The output signals Light1 and Light2 indicate which state is active at any given time
- Red State
 - When the Red state becomes active, the traffic light cycle begins
 - After a short delay, the controller checks for cars waiting at the intersection
 - If it detects at least one car, or if a fixed length of time elapses, then the controller requests a green light by setting `greenLightRequest` to true
 - After making the request, the controller remains in the Red state for a short length of time until it detects that the other traffic signal is red [`~greenLightLocked`]
 - The controller then makes the transition to Green
- Green State
 - When the Green state becomes active, the controller cancels its green light request by setting `greenLightRequest` to false
 - The controller sets `greenLightLocked` to true, preventing the other traffic signal from turning green
 - After some time, the controller checks for a green light request from the other controller [`greenLightRequested`]
 - If it receives a request, or if a fixed length of time elapses, then the controller transitions to the Yellow state
- Yellow State
 - Before transitioning to the Red state, the controller remains in the Yellow state for a fixed amount of time
 - When the Yellow state becomes inactive, the controller sets `greenLightLocked` to false, indicating that the other traffic light can safely turn green
 - The traffic light cycle then begins again

Behavior of Light Controllers

- This table details the activity during the first 300 seconds of the simulation

Time	Description	Light 1	Light2	greenLightRequested	greenLightLocked
t = 0	At the start of the simulation, both traffic lights are red	Red	Red	false	false
t = 6	After 6 seconds (REDDELAY), there are cars waiting in both streets Both traffic lights request a green light by setting greenLightRequested = true	Red	Red	true	false
t = 12	After another 6 seconds (REDDELAY): · Light 1 turns green, setting greenLightLocked = true and greenLightRequested = false · Light 2 requests a green light by setting greenLightRequested = true	Green	Red	false, then true	true
t = 132	After 120 seconds (MINGREENDELAY): · Light 1 turns yellow	Yellow	Red	true	true

Behavior of Light Controllers (continued)

Time	Description	Light 1	Light2	greenLightRequested	greenLightLocked
t = 147	After 15 seconds (YELLOWDELAY): · Light 1 turns red, setting greenLightLocked = false · Light 2 turns green, setting greenLightLocked = true and greenLightRequested = false	Red	Green	false	false, then true
t = 153	After 6 seconds (REDDELAY), Light 1 requests a green light by setting greenLightRequested = true	Red	Green	true	true
t = 267	Light 2 turns yellow 120 seconds (MINGREENDELAY) after turning green	Red	Yellow	true	true
t = 282	After 15 seconds (YELLOWDELAY): · Light 2 turns red, setting greenLightLocked = false · Light 1 turns green, setting greenLightLocked = true and greenLightRequested = false	Green	Red	false	false, then true
t = 288	After 6 seconds (REDDELAY), Light 2 requests a green light by setting greenLightRequested = true	Green	Red	true	true

The cycle repeats until the simulation ends at t = 1000 seconds

Simulink-Stateflow Interface

- Simulink communicates with Stateflow by exchanging data items at ports on the Stateflow “mask” (shown to the right)
- In this example, Simulink provides the number of cars waiting at an intersection to use as an input to the Stateflow model
- Stateflow provides two outputs to control the light selection of the two Semaphores that control traffic in each of the two directions

The screenshot shows the Simulink Model Explorer window. The left pane shows the Model Hierarchy with the 'Traffic Controller' block selected. The right pane shows the Stateflow mask for the 'Traffic Controller' block. The mask has two inputs, 'numCars1' and 'numCars2', and two outputs, 'Light1' and 'Light2'. The inputs are highlighted with red boxes, and the outputs are also highlighted with red boxes. The 'Data numCars2' pane on the right shows the configuration for the 'numCars2' input, including its name, scope, port, and data type.

Name	Scope	Port	Resolve Signal	DataType
numCars1	Input	1		Inherit: Same as Simulink
numCars2	Input	2		Inherit: Same as Simulink
GREENDELAY	Parameter			Inherit: Same as Simulink
MAXREDELAY	Parameter			Inherit: Same as Simulink
REDELAY	Parameter			Inherit: Same as Simulink
YELLOWDELAY	Parameter			Inherit: Same as Simulink
MINGREENDELAY	Parameter			Inherit: Same as Simulink
Light1	Output	1		Enum: LightModeType
greenLightLocked	Local			boolean
greenLightRequested	Local			boolean
Light2	Output	2		Enum: LightModeType

Data numCars2

General Description

Name: numCars2

Scope: Input Port: 2

Size: -1

Complexity: Off

Type: Inherit: Same as Simulink

☐ Lock data type against Fixed-Point tools

Unit (e.g., m, m/s^2, N*m): SI, Eng

inherit

Limit range

Minimum: Maximum:
